

Movies Case Study Project

Ask

The goal of this analysis is to identify the characteristics of top-performing films to guide future decisions regarding content acquisition, recommendation, or investment. In this analysis, we want to answer what characteristics do the best-performing films have in terms of popularity, user ratings, and profitability.

Prepare

In the preparation stage, the data comes from a set of CSV files stored in Kaggle, made available by Rounak Banik under a CC0 license: Metadata about 45,000 movies, with data points including cast, crew, plot keywords, budget, revenue, ratings, release dates, languages, production companies, and more.

The "rating" column represents user ratings, while "popularity" measures visibility or interest. "Revenue" and "budget" allow for the estimation of profitability.

Process

In this processing phase, tables were joined using movie identifiers, numeric columns were converted, JSON-type columns such as genres and keywords were parsed, and empty or erroneous rows were removed. For data cleaning and calculations, I used Python with the pandas library, and for the dashboard, I used Tableau.

Analyze

In this analyzing phase we can see that genres such as Drama, Documentary, and History show high average ratings, indicating a positive reception by users. Ratings don't necessarily reflect a movie's popularity, so that's something to keep in mind. The most popular Production Companies are Warner Bros, Paramount Pictures and Universal Studios, showing a good index for including them in the streaming platform. We also have movies with a high level of profitability based on their revenue what means it could be a hit in terms of customer views on the streaming platform.

Share

I was able to answer the question of what characteristics do the best-performing films have in terms of popularity, user ratings, and profitability. My audience, including the marketing team, benefits from these insights, as data visualization in Tableau helps them quickly grasp

trends and adjust strategies. The presentation is accessible, with clear visuals and concise explanations, ensuring the team can act on these findings.

Key Insights:

- Popularity doesn't guarantee a high rating: some very popular movies aren't necessarily the highest rated by users.
- Movies with the highest estimated profitability combine high revenues with relatively smaller budgets, so they can be good indicators of commercially successful content.
- Genres with the highest average rating can help identify content with higher user ratings, although the number of ratings is also important to consider.
- The estimated profitability does not account for marketing, distribution, or licensing costs; therefore, it should be interpreted as an approximation.

Act

Based on the analysis, my final conclusion is that we should prioritize genres with high ratings and a large number of reviews. Movies with a history of high profitability are strong candidates for inclusion. We should also consider production companies or countries that have demonstrated strong historical performance.

It is recommended to prioritize films that combine high ratings, high popularity, and a history of profitability.

Genres with the best average ratings can help enhance the perceived quality of the catalog, while highly popular movies can help attract users. To make better decisions, it is advisable to cross-reference these variables rather than analyzing them in isolation.
